**REPORT ON RESURVEY OF SEDIMENTATION
CARLYLE RESERVOIR
KASKASKIA RIVER, ILLINOIS, 1999**

1. INTRODUCTION

This report is prepared according to instructions in EM 1110-2-4000, Sedimentation Investigations of Rivers and Reservoirs dated December 15, 1989, and represents the results of the 1999 resurvey of Carlyle Reservoir sedimentation ranges. The purpose of the investigation was to analyze the 1999 resurvey data to determine the distribution of sediment depletion of storage in the reservoir and trap efficiency of the reservoir. Initial operation of the reservoir began on April 1, 1967.

2. LOCATION OF RESERVOIR

Carlyle Reservoir is located in Clinton County, Illinois, on the Kaskaskia River. The dam is approximately 100 miles* above the confluence of the Kaskaskia River and the Mississippi River, and approximately 1 mile upstream of the Town of Carlyle, Illinois. The watershed for the reservoir is 2,680 square miles, or about 46 percent of the total Kaskaskia River Basin. The basin is shown on Plate 1.

3. PURPOSE OF RESERVOIR

Carlyle Reservoir is part of the Kaskaskia River Basin development plan. This plan provides flood control, water supply, storage for navigation releases, recreation, and fish and wildlife conservation. The reservoir is operated jointly with the other projects in the Kaskaskia River Basin.

4. RESERVOIR PERTINENT DATA – DAM AND APPURTENANT STRUCTURES

The Pertinent Data Summary, shown on Page v - vi, contains pertinent data concerning the dam, outlet, and spillway structures; and the elevations, areas, and capacities of the inactive, joint-use, flood control, and surcharge pools.

5. WATERSHED CHARACTERISTICS

The watershed has a total area of 2,680 square miles. The reservoir occupies approximately 90 square miles of this area at flood-control pool (elevation 462.5**). The watershed has a median length of about 120 miles, an extreme width of 57 miles, and an average width of about 22.3 miles. The course of the river contains many bends. The topography of the basin is flat to gently rolling terrain. The principal occupation in the watershed is agricultural with approximately 86 percent of the watershed being cultivated annually.

*A table of factors for converting U.S. customary units of measurement to metric (SI) units is presented on Page iv.

**All elevations (el) cited herein are in feet referred to National Geodetic Vertical Datum.

6. CLIMATE

The climate in the area is relatively moderate. The summers are usually mild with occasional temperatures of 100° F or higher. The winters are generally short and moderate, although temperatures below zero are not uncommon. The minimum and maximum temperatures of record are -34° F during the winter and 115° F during the summer. The average annual temperature is about 55° F. The average monthly temperature ranges from a maximum of 78° F during July, to a minimum of 30° F during January. Summaries of the monthly and annual precipitation and runoff for the watershed are given in Tables 1 and 2.

7. RESERVOIR OPERATION

Carlyle Reservoir was designed to operate jointly with Shelbyville Reservoir in a way that their design-flood outflows can be safely and economically handled by authorized levees downstream. The reservoir outflows are regulated to reduce flood peaks downstream, to affect maximum flood control benefits, and to empty the flood control pool during the normal May through November low-water season. Usually, normal operational outflow does not exceed 4,000 cfs. The monthly reservoir pool hydrograph for the period 1967 through 1999 is shown on Figure 1.

8. RESERVOIR INFLOW

Summaries of the monthly and annual precipitation and runoff data for the watershed are given in Tables 1 and 2. One inch of runoff equals 142,933 acre-feet. Average annual precipitation and inflow for the sediment survey period are tabulated in Items 34 and 35 of ENG. Form 1787, a data summary of reservoir sediment. The average monthly inflow hydrograph for the period 1966 through 1999 is shown on Figure 2.

9. ORIGINAL RESERVOIR SURVEY

Reservoir area and volume were determined from U.S. Geological Survey quadrangle sheets and River and Lakes Commission topographic survey sheets of 1908. The area and volume curves were checked from 1956 topographic reservoir survey sheets. A tabulation of the reservoir storage for 5-foot intervals is shown in Tables 3. Item 46 of ENG Form 1787, gives area and storage (capacity) tabulation at 15-foot intervals for the original survey. Elevations versus capacity curves are shown in Figure 3.

10. TYPE AND SCOPE OF THE INITIAL SEDIMENT SURVEY

There were nine sediment ranges established and surveyed by direct leveling during the period of July 1965 through January 1967 for the purpose of observing sediment distribution and the approximate rate of reservoir storage depletion. Plate 2 shows the locations of the sediment ranges. The cross sections of the ranges for the original survey and each of the resurveys are shown on Plates 3 through 11. Appendix B shows detailed locations of the nine sediment ranges.

11. TYPE AND SCOPE OF SEDIMENT RESURVEYS

Detailed sediment resurveys of the nine sediment ranges by direct leveling and by a Ratheon Recording Depth Sounder, Model EE-119 were made during 1971, 1976, 1982, 1984 and 1999. The 1971 sediment resurvey was conducted from May to August 1971. The average elevation of the reservoir pool during the measurements was about 443.0. The 1976 sediment resurvey was conducted from January to March 1976. The average elevation of the reservoir pool during the measurements was about 440.5. The 1982 resurvey was conducted from September 1982 to February 1983, with most of it being in September 1982. The average pool elevation at this time was about 445.5. The 1984 resurvey was conducted in August and September 1984. The average pool elevation was about 445.0. The 1999 resurvey was conducted in September 1999 with an average pool elevation of 444.5.

Additional ranges were added in the 1982 resurvey and in the 1984 resurvey to better understand the sediment trends throughout the entire reservoir. In 1982, Ranges 3.1A and 3.2A were added, located about 7 miles and 9 miles upstream of the dam, respectively. Ranges 4.1A through 4.5A cross the Kaskaskia River channel only and were first surveyed in 1984. They are located between Ranges 4A and 7A with Range 4.1A about 1,400 feet upstream of Range 4A and Range 4.5A about 2,600 feet upstream of Range 4A. Ranges 4.1A through 4.5A cross only the river channel because of excessive brush, logs, etc. in the overbank areas, which would make surveying impossible. Plotted cross sections of these seven ranges are shown in Appendix A. Plate 1 shows the locations of the ranges in the reservoir, and Appendix B shows their detailed locations.

These additional ranges were not used in the 1999 resurvey. Whenever future reservoir volumes are calculated with data from the additional ranges, comparison cannot be made with any survey done prior to the inclusion of the additional ranges. This is because calculations performed with the additional range data will yield a result different from that obtained without the additional data. Consistency in comparison must be maintained.

12. METHODS OF SEDIMENT COMPUTATIONS

All previous resurveys used the prismoidal formula developed by the U.S. Soil Conservation Service (SCS).

This study however used the average end area method to determine the volume of sediment deposition for the period of 1967 to 1999. For this period calculation, common cross sections (sedimentation ranges) were compared. The area of sediment, in square feet, was determined for each resurveyed cross section at each one-foot elevation interval and the volume of sediment in each horizontal slice was determined by the average of the end area multiplied by the average length between the sections. The equation is expressed as:

$$V = (L * (A_1 + A_2)/2)/43560$$

Symbols used in the above equation are defined as:

V = sediment volume between ranges for a survey period in acre-feet.

A = area at 1-foot interval.

L = average length between the cross sections.

Results of the analysis displaying the differences of area at each one-foot interval are presented in Table 5.

13. SEDIMENT QUANTITIES

A summary of the volume of sediment deposited between each range in the reservoir for the periods 1967-1999 is presented in Figure 4 and Tables 6A, 6B, and 6C. In addition, Figure 5 presents sedimentation by elevation. A summation of the volume of sediment deposited in each reach indicates that during the period 1967-1999 about 2.4 percent of the total reservoir capacity was lost to sedimentation. This is a depletion rate of about 0.07 percent per year.

The 1999 resurvey data show that of the 22,167 acre-feet of sediment calculated to be deposited from 1967 to 1999, about 17,653 acre-feet was deposited within the inactive pool (below elevation 429.5). This decreased the amount of storage in the inactive pool by approximately 50 percent. In the joint-use pool (elevation 429.5 to 445.0), about 8,199 acre-feet of sediment accumulated. This reduced the joint-use pool capacity by 3.5 percent. The flood-control pool experienced a storage increase of about 3,685 acre-feet. The following table summarizes the sediment deposition in Carlyle Lake based on the 1999 resurvey. A 32.5-year time period (April 1, 1967 to September 30, 1999) was used to compute the rates of sediment deposition.

SUMMARY OF CARLYLE RESERVOIR SEDIMENTATION

RESERVOIR PORTION	AMOUNT OF SEDIMENT DEPOSITED 1999-1967 (ACRE-FEET)	ANNUAL RATE OF DEPOSITION 1999-1967 (ACRE-FEET/YR)
Entire Reservoir	22,167	682
Inactive Storage	17,653	543
Joint-Use Storage	8,199	252
Flood-Control Storage	-3,685	-113

The 1999 resurvey also showed that, for the entire reservoir, the greatest amount of sediment was deposited between Ranges 3A and 4A. This section accounted for about 31 percent of the total sediment accumulation. The distance between Ranges 3A and 4A is approximately 5.25 miles, making it the largest section in the reservoir. Almost 59 percent of the total sedimentation was

deposited in the upper part of the reservoir, upstream of Range 3A. The reservoir is approximately 15.1 miles long at the joint-use pool elevation and the distance to Range 3A from the dam is approximately 5 miles.

14. TRAP EFFICIENCY OF THE RESERVOIR

For the period of operation from 1967 to 1999, Carlyle Reservoir has a trap efficiency of 78 percent. This value was determined using Gunnar M. Brune's median curve of Figure F-2 presented in EM 1110-2-4000, Sedimentation Investigations of Rivers and Reservoirs, pgs. F-2, F-4. A capacity-inflow ratio of 0.56 was computed (Item 33, ENG Form 1787) using an average reservoir capacity over the period of operation of approximately 928,900 and an average annual inflow of 1,673,400 acre-feet. Appendix C provides the sediment size distributions based on sediment samples collected in the 1982 resurvey. No sediment samples were collected in 1999.

15. DOWNSTREAM CHANNEL AND RESERVOIR OPERATION

A series of nine retrogression ranges were established downstream of Carlyle Dam to assist in monitoring downstream changes due to reservoir operation. They cover from the U.S. 50 Highway Bridge at River Mile 105.7 to River Mile 102.75 (see Appendix B). A thalweg profile, illustrating the changes in riverbed elevation since reservoir operation began in 1967, is shown in Figure 6. Cross sections of the retrogression ranges are shown in Plates 12 through 20. The 1999 resurvey data indicate that an increase of 17.8 percent was experienced over the river reach between Ranges 1C and 9C. Examination of the cross-sectional plots reveals that most of the volume changes are due to lateral bank movement and erosion, not in bed elevation changes. This bank erosion should continue to be monitored.

16. EFFECT ON WATER SUPPLY CONTRACT

The joint-use pool originally had 232,800 acre-feet of storage, of which 32,692 acre-feet was allocated for water supply. Of the total joint-use storage, only 8,214 acre-feet had been depleted by 1999, a reduction of approximately 3.5 percent. Due to the small amount of storage depleted, the existing Water Supply Contract should not be changed. In the future, if sediment distribution decreases the amount of joint-use storage to the extent that any project purpose is affected, the District Engineer shall make an equitable redistribution of the storage allocations served by the project. Information concerning future sedimentation and any redistribution of storage allocations shall be made available to the Illinois Department of Transportation, Division of Water Resources.

17. SUMMARY

The computed rate of sediment deposition, 682 acre-feet per year is near the predicted rate of 746 acre-feet per year, which was the expected yearly sedimentation rate computed before the operation of the project. This predicted rate was obtained from the suspended sediment and bed-load capacity of the river at the nearest sedimentation station to Carlyle Dam, located at Shelbyville, Illinois. It was also based upon information furnished by the U.S. Department of Agriculture, Soil Conservation Service, in a letter, dated February 28, 1954. The results show that a significant amount of sedimentation is occurring in the inactive storage pool. For the period 1967-1999, 80 percent of the sedimentation occurred below the joint-use pool.

Based on the results of the 1999 resurvey, in 20 years (2019) the inactive pool will have lost approximately 28,513 acre-feet of storage to sediment accumulation, or about 80 percent of its original capacity; the joint-use pool will have lost approximately 13,239 acre-feet of capacity, or about 5.7 percent; while due to an increase in storage, a prediction concerning the flood-control pool is not made at this time. A summary of reservoir sedimentation is shown on ENG. Form 1787.

18. RECOMMENDATION

Current budgeting guidance limits potential funding for future sediment surveys. Funding will be requested to conduct another resurvey in the next five to ten years. However, until the sediment deposition is anticipated to have a significant impact on project operations, funding will be unlikely. At the current rate of sedimentation, in 15 to 20 years the level of funding could justifiably be raised. The decision to do so should be based on an evaluation of the flood events that have occurred and their estimated contribution to loss of available storage.

TABLE 1. Monthly Precipitation and Runoff for Carlyle Reservoir (Jan. 1966 – Dec. 1999).

Month	Maximum Rainfall (inches)	Minimum Rainfall (inches)	Average Rainfall (inches)	Average Runoff (inches)	Runoff (percent)
January	5.04	0.03	1.83	0.50	27.3
February	4.50	0.00	1.71	0.70	40.9

465	1,127,534	1,114,803	1,107,000	1,072,500		1,075,800	1,054,500

* As reported in the Report on Sedimentation, 1976 Resurvey.

** As reported in the Report on Sedimentation, 1982 and 1984 Resurveys. The 1976 capacity was listed as Adjusted. Three values at elevations 430, 445, and 462.5 were computed, while other values were interpolated from elevation – capacity curves.

*** The original capacity was re-determined in 1999 using the average end area method instead of the prismoidal method used in the previous surveys. In addition several cross sections were extended based upon intermediate resurveys that included area that was inaccessible in the original survey. Capacity for elevation 465 was extrapolated.

‡ Capacity for elevation 465 was extrapolated.

47. REMARKS AND REFERENCES

- 1/ Top of movable gates in closed position, includes 1 ft. freeboard. Flood control pool (el. 462.5) used for items 19, 31, 32, 33, 41, 43.
2/ Redetermined in 1999 Resurvey, using average end area method.
3/ Includes 32,692 acre-feet for water supply, remainder for navigation.
4/ Adjusted to reflect that Lake Shelbyville controls 39% of the watershed.
5/ Precipitation data for period extends through Dec. 1983.
6/ 1971 resurvey results were presented in the Report of Sedimentation, 1976 resurvey, and are not shown here due to space limitations.
7/ Period used is 1967-1999.
8/ No sediment samples taken in 1976 and 1999.
