CONVERSION FACTORS, U.S. CUSTOMARY TO METRIC (SI)
UNITS OF MEASUREMENT

U.S. customary units of measurement used in this report can be converted to metric (SI) units as follows:

<u>Multiply</u>	<u>By</u>	<u>To Obtain</u>
inches	25.4	millimetres
feet	0.3048	metres
miles (U. S. statute)	1.609344	kilometres
square miles	2.589988	square kilometres
cubic yards	0.7645549	cubic metres
acre-feet	1233.482	cubic metres
feet per second	0.3048	metres per second
cubic feet per second	0.02831685	cubic metres per second

REPORT ON RESURVEY OF SEDIMENTATION

LAKE SHELBYVILLE

KASKASKIA RIVER, ILLINOIS

1. INTRODUCTION.

This report is prepared according to instructions in EM 1110-2-4000, dated 15 November 1961, and compares the original 1970 survey with the 1974 and 1980 resurveys of the upstream sediment ranges and downstream retrogression ranges for Lake Shelbyville.

The purpose of the investigation was to analyze the 1974 and 1980 resurvey data to determine the distribution of sediment in the lake, and also the trap efficiency of the lake. Initial operation of the reservoir began on 1 August 1970.

2. LOCATION OF RESERVOIR.

Lake Shelbyville is a multi-purpose reservoir located on the Kaskaskia River, one-half mile east and one-fourth mile north of the town of Shelbyville, Illinois. The reservoir extends from the main dam at river mile 221.8 ^{1/} to river mile 280. The watershed for the reservoir is 1,054 square miles. PLATE 1 shows the relationship of the reservoir to the entire basin.

3. PURPOSE OF RESERVOIR.

The purpose of this project is to provide flood protection; to create recreational opportunities; to provide fish and wildlife conservation; to augment water supplies; to enhance water quality; and to augment flows for navigation.

4. RESERVOIR PERTINENT DATA - DAM AND APPURTENANT STRUCTURES.

The Pertinent Data Summary, shown on page iv, contains pertinent data concerning the dam, outlet, and spillway structures, and the elevations, areas and capacities of the inactive, joint-use, flood control, and surcharge pools.

5. WATERSHED CHARACTERISTICS.

The watershed has a total area of 1,054 square miles. The lake occupies approximately 39.5 square miles of this area at the top of flood control pool (el. 626.5).^{2/} The watershed has a length of 58 miles, an extreme width of 35 miles, and an average width of 18 miles. (See PLATE 1)

1/ A table of factors for converting U.S. customary units of measurement to metric (SI) units is presented on page vi.

2/ All elevations (el) cited herein are in feet referred to National Geodetic Vertical Datum.

6. CLIMATE.

The climate of the area is relatively moderate. The summers are usually mild with occasional temperatures of 100°F or slightly higher. The winters are usually short and moderate, although temperatures below zero are occasionally experienced. The average annual temperature in this area is about 55°F and the average monthly temperature varies from a maximum of 78°F during July to a minimum of 30°F during January.

7. RESERVOIR OPERATION.

The objective is to regulate the project to provide flood control to downstream interests and to maintain the pool at seasonal pool elevation as set forth by the Schedule of Release, thus providing water storage for water supply, pollution abatement, fish and wildlife conservation, recreation, and navigation on the lower Kaskaskia River. A minimum release of 10 c.f.s. is required at all times to maintain good downstream water quality. The downstream channel restricts non-damaging releases to 1800 c.f.s. or less during the growing season (1 May through harvest).

8. RESERVOIR INFLOW.

Summaries of the monthly and annual precipitation and runoff data for the watershed are given in TABLES 1 and 2. One inch of runoff equals 56,210 acre-feet. Average annual precipitation and inflow for the sediment survey period are tabulated in Items 34 and 35 of PLATE 54, a data summary of reservoir sediment, ENG. Form 1787. The average monthly inflow hydrograph for the period 1970 through 1980 is shown on PLATE 2. The average monthly pool stage for the same period is shown on PLATE 3.

9. ORIGINAL RESERVOIR SURVEY.

A tabulation of the original capacity for 5-foot intervals is shown in TABLE 3. Item 46 of PLATE 55, ENG Form 1787, gives area and storage (capacity) tabulation at 10-foot intervals for the original survey. Area and capacity curves are shown on PLATE 4.

10. TYPE AND SCOPE OF INITIAL SEDIMENT SURVEY.

There were forty (40) sediment ranges established and surveyed by direct leveling during the period March 1969 - June 1971 for the purpose of observing sediment distribution and the approximate rate of reservoir storage depletion. PLATE 5 shows the location of the pool sediment ranges. The cross-sections of the ranges for the original survey and the 1974 and 1980 resurveys are shown on PLATES 6 through 45. Appendix A shows detailed location of the forty sediment ranges.

11. TYPE AND SCOPE OF SEDIMENT RESURVEYS.

A. Detailed sediment resurveys were made during 1974 and 1980. The dry land portions of the resurveys were conducted by direct leveling. The soundings were performed with a Raytheon, Model 719B, depth recorder which

was used in conjunction with a Motorola Miniranger distance measuring unit which constantly updates the distance from the shore station. The depth recorder was placed in an 18 foot jon boat with a 20 horsepower outboard motor. Horizontal alignment was maintained by communication with walkie-talkies between the boat operator and a person on shore. The person on shore was located at one end of the sedimentation range with a transit sighted on the other end of the range for alignment purposes. Thus, if the boat making the soundings varied off the range, the person on shore manning the transit could communicate with the boat operator by walkie-talkie as to what corrective measure to take.

B. The 1974 resurvey was conducted from February to April 1974. The average pool elevation during the measurements was 603.1. The 1980 sediment resurvey was conducted during November and December 1980. The average pool elevation during the measurements was 596.3. The capacities based on the results of both resurveys are shown in TABLE 3.

12. METHODS OF SEDIMENT COMPUTATIONS.

Several methods have been developed for computing the amount of sediment deposited in a reservoir. The modified - prismoidal method, average depth method and the average end method were used in this report to analyze and compute the volume of sediment deposited. In the analysis, water surface areas were determined using a water surface elevation of 626.5. Cross-sectional range data is tabulated in TABLE 4 and TABLE 5. The three methods used to compute the volume of sediment for the periods of 1970-1974 and 1970-1980 are defined as:

Prismoidal Method - The prismoidal formula used to compute the volume of sediment deposited during the 1974 and 1980 resurveys was derived by the Soil Conservation Service and published as USDA Technical Bulletin No. 524, "Silting of Reservoirs," dated August 1939. For method of computations see pages 158-161.

Average Depth Method - The surface area between two adjacent ranges was multiplied by the average depth of the two ranges to determine the capacity of the segment of reservoir bounded by the two ranges. The average depth of a range equals the cross-sectional area divided by the horizontal length of the range. The equation is expressed as:

$$V = A \times \frac{E_1 + E_2}{W_1 + W_2}$$

2

Average End Method - The average change in cross-sectional area of sediment between two adjacent ranges was multiplied by the length of the segment (L) to determine the net change in volume of sediment bounded by the two ranges. The equation is expressed as:

$$V = \frac{(E_1 + E_2)}{2} \times \frac{L}{43,560}$$

Symbols used in the above equations are defined as:

V = change in sediment volume between ranges for a survey period in acre-feet.

A = surface area between ranges of the segment in acres.

E = net change in cross-sectional area between ranges for a survey period in square feet.

W = horizontal length of the range at crest elevation in feet.

L = length between ranges in feet.

Results of the analysis using the above equations are presented in TABLE 7.

13. SEDIMENT QUANTITIES.

A. The Prismoidal Method was used for final sediment quantities in this report since it was developed specifically for calculating the amount of sediment deposited between two ranges and is well documented and referenced. The Average-Depth and Average-End Methods were used for comparison purposes only. As can be seen in TABLE 7, the Average-Depth Method produced results which totaled approximately 13^{1/4} percent greater than the prismoidal method. The Average-End Method produced results which were about 2^{1/4} percent less. The Average-End Method applies best to areas with fairly uniform widths throughout. Since Lake Shelbyville has numerous inlets and bays along its shoreline, i.e., not constant width between ranges, the Average-End Method should not have produced accurate results, which is shown when compared to the other two methods. The above comparisons were based on the results of the 1980 resurvey.

B. A summary of the area changes of each sediment range along with the volume of sediment deposited between each range in the reservoir for the periods 1970-1974 and 1970-1980 are presented in TABLES 6 and 7, respectively. Calculations using data of the initial 1974 sedimentation resurvey indicate an increase of about 0.66 percent in the total storage between the date of initial operation and April 1974. The results of the 1980 resurvey indicated that about 1.2 percent (8,214 acre-feet) of the capacity in the entire reservoir has been lost between 1970 and 1980. Of the 8,214 acre-feet of sediment deposited, approximately 6,155 acre-feet was deposited within the inactive pool (below el. 573.0). This decreased the storage capacity of the inactive pool by 20 percent. In the joint use pool (el. 573.0 to el. 599.7), there was 1,904 acre-feet of sediment deposited. This reduced the joint-use pool storage by one percent. The remaining sediment was deposited within the flood control pool (above el. 599.7). The

amount is insignificant when compared to the 468,385 acre-feet of flood control storage. The resurvey also showed that the majority of the sediment (84 percent) was deposited from the dam to a point approximately 10 miles upstream (Range 17A is approximately 10 miles upstream from the dam). As can be seen in TABLE 7, the sediment within this 10 mile stretch was distributed fairly evenly. The following table summarizes the sediment deposition for the lake based on the 1980 resurvey:

	<u>AMOUNT OF SEDIMENT DEPOSIT (ACRE-FEET)</u>	<u>RATE OF DEPOSITION (ACRE-FEET/YEAR)*</u>
Entire Reservoir	8,214	775
Inactive Storage	6,155	580
Joint-use Storage	1,904	180
Flood Control Storage	155	15

*Based on 10.6 years, Plate 54, Item 27.

14. TRAP EFFICIENCY OF THE RESERVOIR.

For the period of operation, Lake Shelbyville has a trap efficiency of 100 percent. This computation was based on the method of Gunnar M. Brune, using the capacity - inflow ratio (Item 33, Plate 54), presented in a transaction of the American Geophysical Union, Volume 34, Number 3, June 1953, pages 407-414. TABLE 9 is a tabulation of sieve analysis of sediment samples taken in 1980. Sediment samples were not taken in 1974.

15. DOWNSTREAM CHANNEL AND RESERVOIR OPERATION.

A series of six (6) retrogression ranges cover from mile 220.9 to mile 216.8 (see PLATE 46). The 1974 and 1980 resurveys showed no significant aggradation or degradation occurring. A thalweg profile, including the initial 1970 survey and both the 1974 and 1980 resurveys, is shown on PLATE 47. The plotted retrogression ranges are shown as PLATES 48 through 53. PLATE 47A compares the 1972 tailwater rating curve with the latest available curve, 1977. TABLE 8 shows a tabulation of volume change downstream of the dam. There has only been a slight increase in volume, 3.6 percent, since initial operation. Retrogression range 1C was destroyed when Highway 16 was relocated downstream of Shelbyville Dam. It has not been re-established.

16. SUMMARY.

Based upon the results of the 1980 resurvey, in 50 years of operation the inactive pool will have lost 29,000 acre-feet of capacity, or for all practical purposes, been depleted entirely, and the joint use pool will have lost 9,000 acre-feet of capacity to sediment. Overall, the 775 acre-feet per year deposition rate is 2.7 times higher than the predicted rate of 288 acre-feet per year. The predicted rate was based on samples taken with a U.S. Geological Survey bucket-type sampler at the Shelbyville sediment gaging station. Often times the sedimentation rate will be higher during the first

few years of operation of a reservoir due to the clearing of land in the lake area. This exposes land which once was protected from erosion. Then, until this land once again stabilizes, erosion rates will be higher, therefore increasing the amount of sediment entering the reservoir.

Concerning the results of the 1974 resurvey, the data was reviewed for errors which could have resulted in the increased capacity. No errors were found in the resurvey data. Also, there is no great amount of mining activity or oil well drilling in the area to cause subsidence of the land. The only other reason for the high rate appears to be survey error. The same contractor conducted the 1974 resurvey at Rend Lake, Big Muddy River, Illinois. The results at Rend Lake for the 1974 resurvey also showed an increase in capacity. Therefore, it is possible that the contractor's equipment produced erroneous results. In the future, the data should be reduced as soon as possible, so that questionable data can be adjusted or redone.

17. RECOMMENDATION.

It is recommended that a resurvey be conducted no later than FY 85. Since the 1974 resurvey gave no rate of deposition, there is no way of knowing if the sedimentation rate computed with the 1980 resurvey is increasing, decreasing, or has stabilized. If a complete resurvey is not possible by FY 85, then a partial resurvey consisting of ranges 1A through 17A should be conducted. The area extending upstream from the dam to range 17A was the area of greatest sediment deposition. Therefore, a resurvey of this area would be an indicator as to the tendency of the rate of deposition. After the next resurvey, it may be necessary to modify the Water Supply Contract due to higher than anticipated sediment deposition rates.

47. REMARKS AND REFERENCES														
1/ Elevation of top of gates in closed position. Flood control pool(626.5) was used in items 19,31,32,33,41,43.														
2/ Includes 25,000 acre-feet for water supply(2 yr. supply).														
3/ 25 miles Kaskaskia River and 22 miles West Okaw River.														
4/ 1974 resurvey showed an increase in capacity, therefore this data is not shown.														
5/ For the 1974 resurvey, no samples were taken.														
6/ Based on prismoidal method.														
48. AGENCY MAKING SURVEY U.S. Army Corps of Engrs. LMVD, SLD														
49. AGENCY SUPPLYING DATA														
50. DATE December 1981

TOPO NO. 9

A hand-drawn survey diagram showing the locations of several trees relative to a central point. The central point is marked with a small square and labeled "185'".

- Top Left:** A tree labeled "4" WHITE OAK" is located at a bearing of $9^{\circ} 45'$ from the center.
- Top Right:** A tree labeled "10" WHITE OAK" is located at a bearing of $10^{\circ} 45'$ from the center.
- Bottom Left:** A cluster of trees labeled "1/2" COPPER ROD ELEV=637.73 (PG. 69, BK. I (P) - 1968)" is located at a bearing of $18^{\circ} 15'$ from the center.
- Bottom Center:** A tree labeled "16" WHITE OAK" is located at a bearing of 8° from the center.
- Bottom Right:** A tree labeled "10" WHITE OAK" is located at a bearing of $17^{\circ} 45'$ from the center.
- Bottom Far Right:** A tree labeled "14" WHITE OAK" is located at a bearing of 10° from the center.

The diagram also includes labels for "STATE PARK" and "CREEK". A vertical line labeled "II" is positioned on the right side.
